(54) OPTICAL ISOLATOR

(57)Abstract:

PURPOSE: To provide the small-sized optical isolator which has no wavelength dependency.

CONSTITUTION: A rotary polarizing liquid crystal rotator 2 and a Faraday rotator 3 which change the polarizing direction of light are arranged between a polarizer 1 and an analyzer 4 which pass specific linear polarized light, and a magnetic field 5 is applied to the Faraday rotator 3; and the liquid crystal rotator 2 has exactly opposite rotational angle characteristics from a polarized light rotational angle depending upon the wavelength of the Faraday rotator 3 for reverse-directional incident light to the isolator, and the analyzer 4 has its polarizing direction slanted to the polarizer 1 by the sum of an angle α of polarized light rotation of reference wavelength by the liquid crystal rotator 2 and 45° .

CLAIMS

[Claim(s)]

[Claim 1] The liquid crystal rotator of the optical activity which can change the polarization direction of light between the polarizer which passes the specific linearly polarized light, and an analyzer, The Faraday rotator to which the polarization direction can be changed with the MAG is arranged. And it is the optical isolator which equipped the above-mentioned Faraday rotator with the magnet for generating the Faraday effect. The above-mentioned liquid crystal rotator has an angle-of-rotation property completely contrary to the polarization angle of rotation for which it depended on the wavelength of the above-mentioned Faraday rotator to the incident light of the hard flow to the optical isolator concerned. The above-mentioned analyzer is an optical isolator characterized by only the sum of the polarization angle of rotation in the criteria wavelength by the above-mentioned liquid crystal rotator and 45 degrees having leaned the polarization direction to the above-mentioned polarizer.

DETAILED DESCRIPTION

[Detailed Description of the Invention]

[0001]

[Industrial Application] This invention relates to the optical isolator aiming at a miniaturization.

[0002]

[Description of the Prior Art] In optical communication, the videodisk which can be written in using semiconductor laser etc. as the light source, the optical isolator which prevents the reflected light from an optical fiber, a lens system, and a connector end face is used.

[0003] The conventional optical isolator is shown in drawing 3 and 4. As shown in both drawings, a polarizer 101, the Xtal rotator 102 of optical activity, Faraday rotator 103, and an analyzer 104 arranged the optical axis, and carried out sequential arrangement, and this optical isolator is equipped with the magnet which a magnetic field 105 is given [magnet] and makes Faraday rotator 103 generate the Faraday effect and which is not illustrated. Here, the optical-activity Xtal rotator 102 compensates the polarization angle-of-rotation wavelength dependency of Faraday rotator 103. Moreover, only the sum of a polarization angle of rotation [in / in an analyzer 104 / the criteria wavelength of the optical-activity Xtal rotator 102] and 45 degrees has leaned the polarization direction to the polarizer 101.

[0004] signs that the light of criteria wavelength was introduced into such an optical isolator -- drawing 3 (A) and (B) It explains referring to. Drawing 3 (A) 106-1-5 show the situation of the polarization of light which goes to the forward direction, and after the light (106-1) of the criteria wavelength which goes to the forward direction turns into light (106-2) which is in agreement in the polarization direction with passage of a polarizer 101, it is outputted by the optical-activity Xtal rotator 102 in response to rotation of an include angle α (106-3). And this light (106-3) receives 45 rotations in this direction by Faraday rotator 103, and is the light which rotated only $\alpha+45$ degrees to the polarization direction of a polarizer 101 after passage (106-4). Therefore, this light (106-4) passes the analyzer 104 with which the polarization direction leans and is allotted only $\alpha+45$ degrees to the polarizer 101 (106-5).

[0005] Drawing 3 (B) 107-1-4 show the situation of the polarization of light which goes to hard flow, and only the light (107-2) which corresponds in the polarization direction of an analyzer 104 passes the analyzer 104 concerned. This light (107-2) is $\alpha+45$ degrees (based on the hand of cut in the forward direction.) to the polarization direction of a polarizer 101. It is the same light which rotated below, and after Faraday rotator 103 passage, this light (107-2) receives 45 rotations, and turns into light (107-3) which rotated $\alpha+90$ degrees to the polarization direction of a polarizer 101. And since this light (107-3) turns into light (107-4) which received rotation of $-\alpha$ by the optical-activity Xtal rotator 102 further, and rotated 90 degrees to the polarization direction of a polarizer 101, a polarizer 101 cannot be passed.

[0006] next, the case where a different light from criteria wavelength is introduced -- drawing 4 (A) and (B) It explains referring to. Drawing 4 (A) 108-1-5 show the situation of the polarization of light which goes to the forward direction, and after the light (108-1) of criteria wavelength and different wavelength turns into light (108-2) which was in agreement in the polarization direction with passage of a polarizer 101, it is outputted by the optical-activity Xtal rotator 102 in response to rotation of include-angle $\alpha+\delta$ (108-3). And this light (108-3) receives rotation of 45 degree $+\delta$ in this direction by Faraday rotator 103, and is the light which rotated only $\alpha+2\delta+45$ degree to the polarization direction of a polarizer 101 after passage (108-4). therefore, the light (108-5) outputted from an analyzer 104 will become one times the reinforcement of $\cos^2 2\delta$ to the output light (108-3) from Faraday rotator 103, if loss of an analyzer 104 is disregarded.

[0007] Drawing 4 (B) 109-1-4 show the situation of the polarization of light which goes to hard flow. The light (109-2) which passes an analyzer 104 among the light (109-1) of criteria wavelength and different

wavelength is a light which is rotating $\alpha+45$ degrees to the polarization direction of a polarizer 101, and this light turns into light (109-3) which rotated $+90$ $\alpha+\delta$ to the polarization direction of a polarizer 101 after Faraday rotator 103 passage. Furthermore, since this light receives rotation only for $-(\alpha+\delta)$ by the optical-activity Xtal rotator 102, since the light which passed the Xtal rotator 102 turns into light (109-4) which intersects perpendicularly in the polarization direction of a polarizer 101, it cannot pass a polarizer 101.

[0008]

[Problem(s) to be Solved by the Invention] As mentioned above, in order to compensate the polarization angle-of-rotation wavelength dependency of Faraday rotator 103 with the conventional optical isolator, the optical-activity Xtal rotator 102 is used. However, the problem of becoming large has the about double figures thickness of the Xtal rotator 102 required since it is small about double figures as compared with the polarization rotation ability of Faraday rotator 103, in order that the polarization rotation ability of the optical-activity Xtal rotator 102 may compensate the wavelength dependency of Faraday rotator 103 from Faraday rotator 103. That is, in the former, when it is going to compensate the wavelength dependency of Faraday rotator 103, there is a problem that the whole optical-isolator size will large-sized-size.

[0009] In this invention, it aims at compensating the wavelength dependency of Faraday rotator and offering an optical isolator with small whole size in view of such a situation.

[0010]

[Means for Solving the Problem] The optical isolator of this invention which attains said purpose The liquid crystal rotator of the optical activity which can change the polarization direction of light between the polarizer which passes the specific linearly polarized light, and an analyzer, The Faraday rotator to which the polarization direction can be changed with the MAG is arranged. And it is the optical isolator which equipped the above-mentioned Faraday rotator with the magnet for generating the Faraday effect. The above-mentioned liquid crystal rotator has an angle-of-rotation property completely contrary to the polarization angle of rotation for which it depended on the wavelength of the above-mentioned Faraday rotator to the incident light of the hard flow to the optical isolator concerned. The above-mentioned analyzer is characterized by only the sum of the polarization angle of rotation in the criteria wavelength by the above-mentioned liquid crystal rotator and 45 degrees having leaned the polarization direction to the above-mentioned polarizer.

[0011]

[Function] A polarization angle of rotation becomes reverse in the forward direction and hard flow, and, as for Faraday rotator, there is a wavelength dependency in this polarization angle of rotation. On the other hand, a liquid crystal rotator has the polarization angle of rotation in which a polarization angle of rotation has the same and, same magnitude wavelength dependency as Faraday rotator in the forward direction and hard flow. Therefore, the wavelength dependency of Faraday rotator is compensated by the liquid crystal rotator of optical activity.

[0012]

[Example] Hereafter, this invention is explained based on an example.

[0013] The optical isolator of this example is shown in drawing 1 and 2. As shown in both drawings, this optical isolator carried out sequential arrangement of a polarizer 1, the liquid crystal rotator 2 of optical activity, Faraday rotator 3, and the analyzer 4, where that optical axis is arranged, and is equipped with the magnet which a magnetic field 5 is given [magnet] and makes Faraday rotator 3 generate the Faraday effect and which is not illustrated. Here, the optical-activity liquid crystal rotator 2 compensates the polarization angle-of-rotation wavelength dependency of Faraday rotator 3. Moreover, only the sum of a polarization angle of rotation and 45 ** has leaned the polarization direction to the polarizer 1. [in / in an analyzer 4 / the criteria wavelength of the optical-activity liquid crystal rotator 2]

[0014] Here, the optical-activity liquid crystal rotator 2 has the property of always rotating the passing light in this direction. That is, the light of criteria wavelength is drawing 1 (A). In passing to the forward direction so that it may be shown, only α receives rotation, and it is drawing 1 (B). If it is based on the hand of cut of the forward direction when passing to hard flow so that it may be shown - Only α will receive rotation. Moreover, it has set up so that the polarization angle of rotation of the optical-activity liquid crystal rotator 2 may compensate the wavelength dependency of Faraday rotator 3 depending on wavelength. That is, it is drawing 2 (A) by making the same the increment in the polarization angle of rotation depending on the wavelength of Faraday rotator 3 and the optical-activity liquid crystal rotator 2 (decrement). Although only 2δ is rotated too much from criteria wavelength in the forward direction so that it may be shown, it is drawing 2 (B). In hard flow, a wavelength dependency will be offset by Faraday rotator 3 and the optical-

activity liquid crystal rotator 2 so that it may be shown.

[0015] The twisted pneumatic (TN) liquid crystal as an example of the optical-activity liquid crystal rotator 2 has the transmission coefficient T of light shown by the degree type.

[0016]

[Equation 1]

$$T = \frac{\sin^2\left(\frac{\pi}{2}\sqrt{1+u^2}\right)}{1+u^2}$$

[0017] Here, it is $u=2d\delta\text{tan}/\lambda$ and d is [a refractive-index difference and lambda of the thickness of liquid crystal and delta tan] the wavelength of light. Although it turns out that the permeability of light changes with wavelength from the upper type, this is for a polarization angle of rotation to be dependent on wavelength. That is, by using this property, as mentioned above, the wavelength dependency of Faraday rotator 3 can be compensated. And about double figures thickness of the optical-activity liquid crystal rotator 2 can be made small compared with the Xtal rotator, and can attain the miniaturization of the optical isolator itself. In addition, it cannot be overemphasized that the liquid crystal rotator 2 is not what is limited to the above-mentioned TN liquid crystal.

[0018] signs that the light of criteria wavelength was introduced into the optical isolator of this example -- drawing 1 (A) and (B) It explains referring to. Drawing 1 (A) 6-1-5 show the situation of the polarization of light which goes to the forward direction, and after the light (6-1) of the criteria wavelength which goes to the forward direction turns into light (6-2) which is in agreement in the polarization direction with passage of a polarizer 1, it is outputted by the optical-activity liquid crystal rotator 2 in response to rotation of an include angle (6-3). And this light (6-3) receives 45 rotations in this direction by Faraday rotator 3, and is the light which rotated only alpha+45 degrees to the polarization direction of a polarizer 1 after passage (6-4). Therefore, this light (6-4) passes the analyzer 4 with which the polarization direction leans and is allotted only alpha+45 degrees to the polarizer 1 (6-5).

[0019] Drawing 1 (B) 7-1-4 show the situation of the polarization of light which goes to hard flow, and only the light (7-2) which corresponds in the polarization direction of an analyzer 4 passes the analyzer 4 concerned. This light (7-2) is alpha+45 degrees (based on the hand of cut in the forward direction.) to the polarization direction of a polarizer 1. It is the same light which rotated below, and after Faraday rotator 3 passage, this light (7-2) receives 45 rotations, and turns into light (7-3) which rotated alpha+90 degrees to the polarization direction of a polarizer 1. And since this light (7-3) turns into light (7-4) which received rotation of -alpha by the optical-activity liquid crystal rotator 2 further, and rotated 90 degrees to the polarization direction of a polarizer 1, a polarizer 1 cannot be passed.

[0020] next, the case where a different light from criteria wavelength is introduced -- drawing 2 (A) and (B) It explains referring to. Drawing 2 (A) 8-1-5 show the situation of the polarization of light which goes to the forward direction, and after the light (8-1) of criteria wavelength and different wavelength turns into light (8-2) which was in agreement in the polarization direction with passage of a polarizer 1, it is outputted by the optical-activity liquid crystal rotator 2 in response to rotation of include-angle alpha+delta (8-3). And this light (8-3) receives rotation of 45 degree +delta in this direction by Faraday rotator 3, and is the light which rotated only alpha+2delta+45 degree to the polarization direction of a polarizer 1 after passage (8-4). therefore, the light (8-5) outputted from an analyzer 4 will become one times the reinforcement of cos2 2delta to the output light (8-3) from Faraday rotator 3, if loss of an analyzer 4 is disregarded.

[0021] Drawing 2 (B) 9-1-4 show the situation of the polarization of light which goes to hard flow. The light (9-2) which passes an analyzer 4 among the light (9-1) of criteria wavelength and different wavelength is a light which is rotating alpha+45 degrees to the polarization direction of a polarizer 1, and this light turns into light (9-3) which rotated +90 alpha+delta to the polarization direction of a polarizer 1 after Faraday rotator 3 passage. Furthermore, since this light receives rotation only for - (alpha+delta) by the optical-activity liquid crystal rotator 2, since the light which passed the liquid crystal rotator 2 turns into light (9-4) which intersects perpendicularly in the polarization direction, it cannot pass a polarizer 1.

[0022] As explained above, the optical isolator of this example compensates the wavelength dependency of Faraday rotator 3 with the liquid crystal rotator 2, and can call it a small optical isolator without the wavelength dependency of incident light. In addition, in the above-mentioned configuration, it cannot be overemphasized that the same effectiveness is acquired in arrangement of Faraday rotator 3 and the liquid crystal rotator 2 even if reverse.

[0023]

[Effect of the Invention] As explained above, the polarization angle of rotation over wavelength has amended the polarization angle-of-rotation wavelength dependency of Faraday rotator using a completely reverse liquid crystal rotator to the polarization angle of rotation of Faraday rotator, and an optical isolator without a wavelength dependency can be constituted. under the present circumstances, since polarization rotation ability of a liquid crystal rotator can be made larger than Faraday rotator, it can come out to make thin thickness for compensating the wavelength dependency of Faraday rotator, and, so, it can make size of the whole optical isolator small.

(54)【発明の名称】 光アイソレータ

(57)【要約】

【目的】 波長依存性のない小形の光アイソレータを提供する。

【構成】 特定の直線偏光を通過させる偏光子1及び検光子4の間に光の偏光方向を変化させることができる旋光性の液晶回転子2と、ファラデー回転子3とを配置し、且つファラデー回転子3には磁場5を与え、液晶回転子は当該アイソレータへの逆方向の入射光に対して上記ファラデー回転子3の波長に依存した偏光回転角と全く逆の回転角特性を有し、検光子4は液晶回転子2による基準波長における偏光回転角 α と45度との和だけ偏光子1に対して偏光方向を傾ける。

(2)

特開平5-241100

1

【特許請求の範囲】

【請求項1】 特定の直線偏光を通過させる偏光子及び検光子の間に、光の偏光方向を変化させることができる旋光性の液晶回転子と、磁気によって偏光方向を変化させることができるファラデー回転子とを配置し、且つ上記ファラデー回転子にファラデー効果を生じさせるための磁石を具えた光アイソレータであって、上記液晶回転子は当該光アイソレータへの逆方向の入射光に対して上記ファラデー回転子の波長に依存した偏光回転角と全く逆の回転角特性を有し、上記検光子は上記液晶回転子による基準波長における偏光回転角と45度との和だけ上記偏光子に対して偏光方向を傾けてあることを特徴とする光アイソレータ。

【発明の詳細な説明】

【0001】

【産業上の利用分野】 本発明は、小形化を図った光アイソレータに関する。

【0002】

【従来の技術】 半導体レーザ等を光源として用いる光通信、書き込み可能なビデオディスク等においては、光ファイバ、レンズ系、コネクタ類端面からの反射光を防止する光アイソレータが用いられる。

【0003】 従来の光アイソレータを図3、4に示す。両図に示すように、この光アイソレータは偏光子101、旋光性の水晶回転子102、ファラデー回転子103及び検光子104が光軸をそろえて順次配置したものであり、磁場105を与えてファラデー回転子103にファラデー効果を生じさせる図示しない磁石を具えている。ここで、旋光性水晶回転子102はファラデー回転子103の偏光回転角波長依存性を補償するものである。また、検光子104は、旋光性水晶回転子102の基準波長における偏光回転角と45度との和だけ偏光子101に対して偏光方向を傾けてある。

【0004】 このような光アイソレータに基準波長の光を導入した様子を図3(A)、(B)を参照しながら説明する。図3(A)の106-1～5は順方向に進む光の偏光の様子を示し、順方向に進む基準波長の光(106-1)は偏光子101の通過によりその偏光方向に一致する光(106-2)となった後、旋光性水晶回転子102により角度 α の回転を受けて出力される(106-3)。そして、この光(106-3)はファラデー回転子103により同方向に45度の回転を受け、通過後には偏光子101の偏光方向に対して $\alpha+45$ 度だけ回転した光となっている(106-4)。よって、この光(106-4)は、偏光子101に対して偏光方向が $\alpha+45$ 度だけ傾けて配されている検光子104を通過する(106-5)。

【0005】 図3(B)の107-1～4は逆方向に進む光の偏光の様子を示し、逆方向に進む基準波長の光(107-1)は検光子104の偏光方向に一致する光(1

2

07-2)のみ当該検光子104を通過する。この光(107-2)は偏光子101の偏光方向に対して $\alpha+45$ 度(順方向での回転方向を基準とする。以下同じ)回転した光であり、この光(107-2)はファラデー回転子103通過後には45度の回転を受け、偏光子101の偏光方向に対して $\alpha+90$ 度回転した光(107-3)となる。そしてこの光(107-3)はさらに旋光性水晶回転子102により $-\alpha$ の回転を受け、偏光子101の偏光方向に対して90度回転した光(107-4)となるので、偏光子101を通過することはできない。

【0006】 次に、基準波長と異なる光を導入した場合を図4(A)、(B)を参照しながら説明する。図4(A)の108-1～5は順方向に進む光の偏光の様子を示し、基準波長と異なる波長の光(108-1)は偏光子101の通過によりその偏光方向に一致した光(108-2)となった後、旋光性水晶回転子102により角度 $\alpha+\delta$ の回転を受けて出力される(108-3)。そして、この光(108-3)はファラデー回転子103により同方向に45度+ δ の回転を受け、通過後には偏光子101の偏光方向に対して $\alpha+2\delta+45$ 度だけ回転した光となっている(108-4)。したがって、検光子104から出力される光(108-5)は検光子104の損失を無視すると、ファラデー回転子103からの出力光(108-3)に対して $\cos^2 2\delta$ 倍の強度となる。

【0007】 図4(B)の109-1～4は逆方向に進む光の偏光の様子を示している。基準波長と異なる波長の光(109-1)のうち、検光子104を通過する光(109-2)は偏光子101の偏光方向に対して $\alpha+45$ 度回転している光であり、この光はファラデー回転子103通過後には偏光子101の偏光方向に対して $\alpha+\delta+90$ 度回転した光(109-3)となる。さらに、この光は旋光性水晶回転子102により $-(\alpha+\delta)$ だけ回転を受けるので、水晶回転子102を通過した光は偏光子101の偏光方向に直交する光(109-4)となるため、偏光子101を通過することはできない。

【0008】

【発明が解決しようとする課題】 前述したように、従来の光アイソレータでは、ファラデー回転子103の偏光回転角波長依存性を補償するために旋光性水晶回転子102を用いている。しかし、旋光性水晶回転子102の偏光回転角は、ファラデー回転子103の偏光回転角に比較して二桁程度小さいため、ファラデー回転子103の波長依存性を補償するために必要な水晶回転子102の厚みもファラデー回転子103より二桁程度大きくなってしまいう問題がある。すなわち、従来においては、ファラデー回転子103の波長依存性を補償しようとすると、光アイソレータの全体サイズが大形化してしまうという問題がある。

(4)

特開平5-241100

5

-1~5は順方向に進む光の偏光の様子を示し、基準波長と異なる波長の光(8-1)は偏光子1の通過によりその偏光方向に一致した光(8-2)となった後、旋光性液晶回転子2により角度 $\alpha + \delta$ の回転を受けて出力される(8-3)。そして、この光(8-3)はファラデー回転子3により同方向に45度+ δ の回転を受け、通過後には偏光子1の偏光方向に対して $\alpha + 2\delta + 45$ 度だけ回転した光となっている(8-4)。したがって、検光子4から出力される光(8-5)は検光子4の損失を無視すると、ファラデー回転子3からの出力光(8-3)に対して $\cos^2 2\delta$ 倍の強度となる。

【0021】図2(B)の9-1~4は逆方向に進む光の偏光の様子を示している。基準波長と異なる波長の光(9-1)のうち、検光子4を通過する光(9-2)は偏光子1の偏光方向に対して $\alpha + 45$ 度回転している光であり、この光はファラデー回転子3通過後には偏光子1の偏光方向に対して $\alpha + \delta + 90$ 度回転した光(9-3)となる。さらに、この光は旋光性液晶回転子2により $-(\alpha + \delta)$ だけ回転を受けるので、液晶回転子2を通過した光は偏光方向に直交する光(9-4)となるため、偏光子1を通過することはできない。

【0022】以上説明したように、本実施例の光アイソレータはファラデー回転子3の波長依存性を液晶回転子2で補償し、入射光の波長依存性のない小形の光アイソレータといえる。なお、上記構成において、ファラデー回転子3と液晶回転子2の配置を逆にしても同様の効果が得られることは言うまでもない。

【0023】

6

【発明の効果】以上説明したように、ファラデー回転子の偏光回転角波長依存性を波長に対する偏光回転角がファラデー回転子の偏光回転角に対して全く逆である液晶回転子を用いて補正しており、波長依存性のない光アイソレータを構成することができる。この際、液晶回転子の偏光回転能はファラデー回転子より大きくすることができるため、ファラデー回転子の波長依存性を補償するための厚みを薄くすることができ、それ故、光アイソレータ全体のサイズを小さくすることができる。

【図面の簡単な説明】
